of Engineering (ME) Computer Science Comparison of three direct optical techniques for choroidal thickness measurement. To evaluate the repeatability and precision of three different optical coherence
tomography (OCT) protocols for choroidal thickness measurement in healthy subjects. Six healthy volunteers were enrolled. The subfoveal choroid was imaged using red-free (695-750 nm), infrared (880-910
nm), and infrared with enhanced depth (1310-1420 nm) imaging. The infrared and infrared with enhanced depth (1310-1420 nm) protocols were repeated at three different points and the scans were averaged.
The red-free protocol was performed at one fixed point. Four-quadrant scans from each of the four quadrants were averaged. Three repeated measurements were acquired on each subject. Coefficients of
variation (CV) for repeatability and coefficient of correlation (CC) with mean choroidal thickness were calculated for all protocols. The averaged CV was 2.85% for the red-free technique, 5.50% for the infrared
protocol and 3.67% for the infrared with enhanced depth protocol. The correlation coefficient was 0.970, 0.961, and 0.965, respectively. These data show a good agreement for the red-free and infrared
protocols. The infrared with enhanced depth protocol, with an averaged coefficient of correlation of 0.965, also shows a good agreement with the average.Q: Mysql. To select rows by group in a tuple

Gonococcal disease in children has become difficult to treat because of a gradual shift in the predominant organisms, and the use of the extended-spectrum cephalosporins. The pathogenesis of the disease is probably related to an incomplete immunologic response to group A beta-hemolytic streptococci in the oropharynx. Although the development of an overt rheumatic fever appears to be rare in children, it is the principal cause of morbidity. A rheumatic carditis, or endocarditis, develops in 1% to 3% of untreated children and in more than 50% of children with the untreated sequelae of rheumatic fever. The early signs of rheumatic fever and rheumatic carditis may be clinically identical to those caused by other diseases. Because the clinical features of these diseases are indistinguishable, physical examination is of little value in the

initial diagnosis. The most useful and sensitive examination is echocardiography. Culture of blood is a more reliable method of diagnosing the disease. The optimum treatment remains unknown.

Antibiotic prophylaxis is the treatment of choice, but there is limited data on the efficacy of this
